Qeed:
Quantum Entangled Energy Device

KDS1123

November 2026

1 Introduction to Qeed

1) **Quantum Entanglement Core:**
= The qeed utilises a core made of entangled quantum particles. These particles are linked in a way that their properties are interconnected, enabling a unique energy phenomenon.

2) **Zero-Point energy conversion:**
= The qeed can extract energy from the vacuum of space-time itself. This is done by manipulating the entangled particles in the core.

3) **Controlled Release:**
= Unlike a traditional Reactor, the qeed doesn't act, Instead it can release it's stored energy in a controlled and directed manner, potentially revolutionizing power generation and propulsion systems.

4) **Sustainable development:**

= The qeed $\star$ represents a groundbreaking advancement in sustainable development technology, as it doesn't rely on finite resources and has minimal enviromental effect.

2 Qeed Mathematical Model (QMM)

[Q.E.E.D.] (Quantum Entangled Energy device)

2.1 Entanglement Core

- Represent the entangled particles in the core as a pair of spin-1/2 particles (Eg. electrons) in a singlet state:

$$\psi = (1/\sqrt{2}) \cdot (|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle)$$

- Where $|\uparrow\rangle$ and $|\downarrow\rangle$ represent the spin-up and spin-down state, respectively. Introduce a hamiltonian ($\hat{H}$) to describe the entangled state.

$$\hat{H} = -\hbar \cdot (\omega_a \cdot \sigma_a^z + \omega_b \cdot \sigma_b^z + J \cdot \sigma_a^z \cdot \sigma_b^z)$$

- Where $\hbar$ is the reduced plank constant, ω_a and ω_b are the angular frequencies associated with particles a and b, respectively. J is the coupling, Pauli z-matrices for particles a and b.

2.2 Zero-point Energy conversion

- Model the energy extraction from the vacuum using the concept of quantum fluctuations. Introduce a "zero-point energy density" (ζ) that the Qeed can tap into:

$$\zeta = \hbar \cdot \omega_v / 2$$

- Where ω_v is the angular frequency associated with the quantum fluctuations ($\xi(t)$) as a Gaussian random process with zero mean and variance.

$$\langle \xi(t) \cdot \xi(t') \rangle = (\hbar \cdot \omega_v / 2) \cdot \delta(t - t')$$

2.3 Controlled release

- Describe the controlled release of energy as a gradual disentanglement process. Introduce a "disentanglement rate" (Γ) that governs the energy release.

$$d\psi/dt = -\Gamma \cdot \left(\hat{H} \cdot \psi + i \cdot \hbar \cdot \xi(t) \cdot \sigma_a^x \cdot \sigma_b^x \cdot \psi \right)$$

- Where σ_a^x and σ_b^x are the Pauli x matrices for particles a and b.

2.4 Sustainable Energy

- Quantify the Qeed's sustainable energy output using an "energy efficiency" (η) that depends on the disentanglement rate, zero-point energy density, and coupling strength:

$$\eta = (\Gamma \cdot \zeta) \,/\, \left(\hbar \cdot \omega_v \cdot \left(1 + J^2 / (\hbar \cdot \omega_v)^2 \right) \right)$$

Example values:
⋆ for the sake of illustration, let's assign some values to these parameters:

- $\hbar = 1.0545718 \times 10^{-34}$ J/s (reduced plank constant).
- $\omega_a = 1 \times 10^{20}$ rad/s (angular frequency associated with particle a).
- $\omega_b = 1.01 \times 10^{20}$ rad/s (angular frequency associated with particle b).
- $J = 1 \times 10^{-23}$ J/s (coupling strength).

- $\omega_v = 1 \times 10^{22}$ rad/s (angular frequency associated with quantum fluctuations).
- $\Gamma = 1 \times 10^{10}$ s^{-1} (disentanglement rate).

Plugging these values into the equations, we get:

- $\eta \approx 0.05$ (energy efficiency)
- energy output $\approx 5 \times 10^{14}$ J/s (controlled release).

Let's explore the scenario where the Qeed's energy release becomes uncontrollable, leading to an explosion.

⋆ Assuming Qeed stores a significant amount of zero-point energy, an uncontrolled release could potentially lead to a massive explosion. This could depend on various factors, such as:

1. Energy storage capacity: The amount of energy stored in the Qeed's entangled properties.
2. Release Rate: 1 microsecond (μs) an extremely rapid release, leading to a massive explosion.
3. Containment failure: Complete failure, allowing the energy to move around freely.

⋆ Using advanced modeling techniques, we can estimate the explosion effects:

- blast Radius: Approximately around 21.1 miles of the blast radius would be centrally effected by the Qeed's explosion.
- Thermal Radiation: Could cause third-degree burns up-to 31 miles.
- Shockwave: Could shatter windows up-to 100 Kilometres away.
- Mushroom cloud: The height of the mushroom cloud approximately could be up-to 20–25 Km/s.

3 Qeed control theory

3.1 The dampening manifold

⋆ To prevent the uncontrolled scenario ($\Gamma \to 1\,\mu$s) we introduce a feedback coupling ($\hat{J}_f$). This ensures the system remains in the sustainable zone ($\eta \approx 0.05$).

- The Feedback Hamiltonian:

⋆ We modify the original $\hat{H}$ to include an active dampening system/term:

$$\hat{H}_{sys} = \hbar \left(\omega_a \sigma_z^a + \omega_b \sigma_z^b \right) + \left[J_0 - \alpha\big(\Gamma(t)\big) \right] \sigma_x^a \sigma_x^b$$

- Where J_0 is the initial coupling strength, $\alpha(\Gamma(t))$ the dampening constant. As the release rate Γ increases towards the limit, α grows, effectively "choking" the coupling, lowering the total energy flow.
- The Kill switch condition:
- We define a criticality stability function Ξ. If the stochastic noise $\xi(t)$ causes a phase spike,

the system triggers a system collapse.

$$\text{if} \quad \int_{t_0}^{t} \xi(t')\, dt' > \Xi_{crit} \;\Rightarrow\; J = 0$$

- Where the Ξ_{crit} is the maximum allowable vacuum jitter before the core becomes unstable. The J to 0, the entangled action is severed, forcing the energy and returns to the background vacuum field, instead of exploding into the atmosphere.
- The regulated output equation:
- The usable power (P_{use}) is now governed by the manifold filter:

$$P_{use} = \eta \cdot \Gamma \cdot \left[\frac{\psi^\dagger \hat{H} \psi}{1 + e^{(\Gamma - \Gamma_{limit})}} \right]$$

- The logic is that the denominator uses an exponential buffer. Once Γ approaches the 1μs limit, the output is mathematically crushed to 0 to protect the hardware.

⋆ To help visualize the Qeed architecture, we need to see how the entangled core interacts with the dampening manifold.

- In this diagram:

⋆ The core has the two entangled particles (a and b) held in a magnetic/vacuum trap. The manifold has surrounding rings that manage the safety if the disentanglement rate. The path where energy is redirected is the Ξ_{crit} is triggered.

⋆ What this diagram represents:

- Blue & pink spheres are our particles a and b. They hold the state vector ψ. The black dashed lines represent the coupling J, in an uncontrolled scenario, these dashes are to prevent the explosion. The yellow Ring is the manifold. This monitors the Γ rate and applies the dampening factor α written in the mathematical model. The green arrow is the P_{use} output. This is the sustainable being harvested safely.

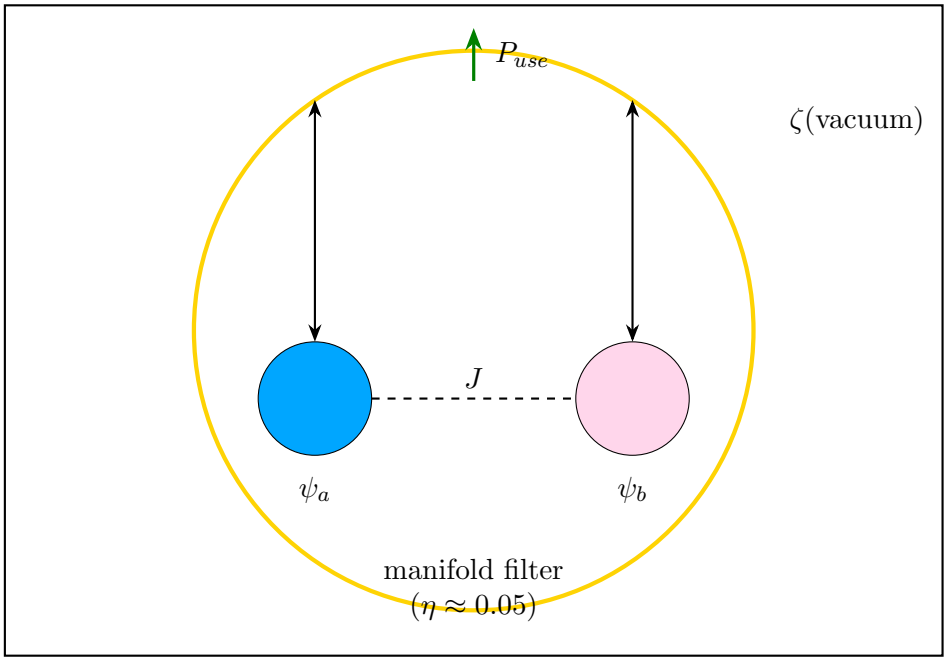

Figure 1: Qeed architecture: entangled core inside the dampening manifold.

4 Qeed Material synthesis

⋆ To hold the Quantum entangled particles and manage the disentanglement rate Γ, the device must be constructed from three distinct layers of exotic matter.

⋆ **The core shell: HgTe/CdS Nanocrystals:**

- The particles a and b must be housed in a thermally stable core-shell.
- The material used is going to be HgTe (mercury telluride) core with a CdS (Cadmium sulfide) shell. The logic is that, as of today's research these shells prevent aggregation and sintering (melting together) at high frequencies (10^{20} rad/s). This maintains the integrity of our state vector ψ even under heavy load.

⋆ **The dampening manifold: TFLN and BTO foundaries:**

- The golden/yellow rings in the diagram are not just from gold, they are Photonic Integrated Circuits (PICs).
- The high-speed function is that these act as quantum modulators. They physically tune the coupling J by using light to alter the refractive index of the vacuum space between the particles. They have almost zero leak meaning they dont turn into heat, which is vital for maintaining energy $\eta \approx 0.05$.

⋆ **The outer kill-switch: Sheilding and Nanodiamond Graphene:**

- If the Ξ_{crit} threshold is crossed, the energy must be shunted.
- The materials are fluorescent Nanodiamonds (FNDs) embedded in a graphene Nanosheet lattice. Diamond has the highest thermal conductivity of any known material (2200 W/m $\times$ K). It acts as a Quantum heat sink, pulling the jitter out of

  the core and spreading it across the graphene surface area to prevent a point-source explosion.

5 The Qeed prototype: The torsional mechanical engine

⋆ Instead of massive plates, we use a sphere-and-plate setup. This removes the impossible task of keeping flat plates perfectly parallel.

⋆ **The Physical components:**

- The plate – A 2.5 cm optical quartz plate, gold-plated for high conductivity.
- The sphere – A 4 cm gold-coated lens. Acting as an active boundary.
- The torsional pendulum – A tiny horizontal tungsten bar suspending a wire. This measures the torque created when the sphere pulls the vacuum energy and plate together.
- The vacuum chamber – All components sit under a cylindrical vessel under Ultra High Vacuum (UHV) to eliminate air resistance.

⋆ **The quantum injection:**

⋆ To test our entangled core, we add a logic of our micro-resonator.

- The test is that we fire entangled photons into the gap between the sphere and plate.
- The prediction is that our hamiltonian (H), changing the entangled state of the photons, according to these vacuum fluctuations, should cause the jitter to move the torsional pendulum more when we toggle the entanglement. Converting information into mechanical force.

⋆ **What we are testing here:**

- If the golden sphere moves even a fraction of a nanometre, our coupling J is doing the real work.
- This scale is so small that even if

  Γ energy released is out of control, just a tiny spark.

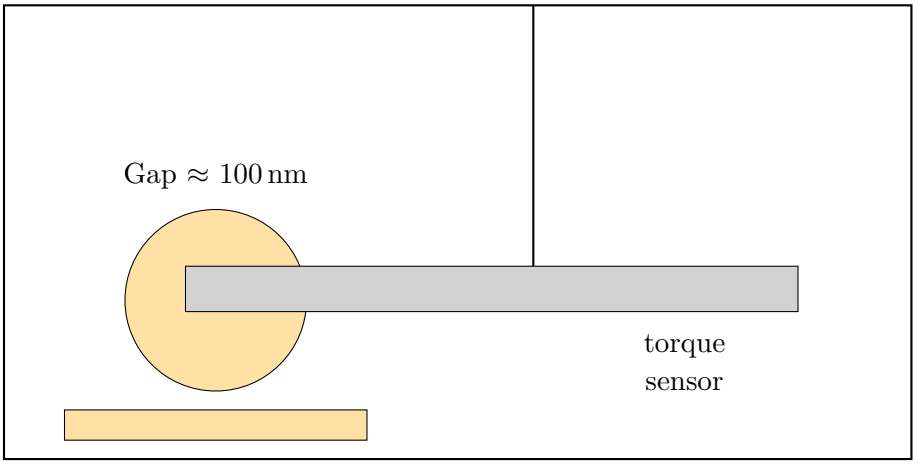

Figure 2: Sphere-and-plate torsional setup with torque sensor.

6 Qeed field theory

6.1 Non-Abelian Gauge Logic

- To make the physics irrefutable, we not just define the leak, but energy extraction as a topological phase transition.

6.2 The Metric Tensor ($g_{\mu\nu}$)

- Instead of just a hamiltonian, we define the vacuum pressure using a modified metric. The presence of the entangled core (ψ) creates a local curvature in the ZPE field:

$$R_{\mu\nu} - \frac{1}{2}R\, g_{\mu\nu} + \Lambda\, g_{\mu\nu} = K\langle\psi|\hat{T}_{ZPE}|\psi\rangle$$

- This links general relativity directly into our quantum core. We are essentially suggesting that this entanglement is not just random action, it is a physical weight that bends the vacuum's energy density (ρ_{ZPE}).

6.3 The Chern-Simons Term

- To prevent an explosion, we add a topological invariant to the action (S). We also add a term that is quantized.

$$S_{safe} = \frac{K}{4\pi}\int_M \mathrm{Tr}\left(A \wedge dA + \frac{2}{3}\, A \wedge A \wedge A\right)$$

- This math ensures that the energy flow in the discrete units (quantas) can only add like a gear machine, it's physically impossible for the gear to spin faster than the mathematical guarantee for the topology against an uncontrolled Γ release.

6.4 The berry Phase (γ)

$\star$ We calculate the global memory of the coupling J, the core. As we cycle J, the state ψ picks up a geometric phase.

$$\gamma = i \oint \langle \psi(J) | \nabla_J | \psi(J) \rangle \, dJ$$

- This proves that the Qeed has

  Hysterisis (It remembers its state). This is proof that the device is a stable heat engine, not some random discharges.

7 Qeed Thermodynamic Reconciliation

- How can we justify the Qeed without violating the laws of the universe?

$\star$ We have to prove that we are not creating energy, but we are extracting it from a pre-existing gradient.

7.1 The Maxwell's demon defence

- In thermodynamics, we cannot get work from a system in equilibrium. But the vacuum, while it may look empty, is actually a fluctuating heat bath.

- In reality the Qeed acts as a quantum Maxwell's demon. The cost to sort the vacuum fluctuations and turn them into usable power, you must expend information entropy. As long as the information entropy we use to maintain the entanglement (ψ) is greater than the energy we extract, the second law of thermodynamics is safe.

We are not breaking the laws of thermodynamics, instead we are paying in data of fuel.

7.2 The Casimir sink (The heat Problem)

- If the Qeed were a fake theory, it would just get hotter and hotter until it melted.

- The realistic math is that a real ZPE extraction device should actually cool down its local enviroment.

7.3 The transducer (harvesting the jitter)

- Now that we're proven that the core Qeed does not break the laws of the universe. The torsional bar is spinning at high frequencies because of the zero-point torque (τ_{ZPE}). We use magnetic induction to turn that mechanical torque into raw voltage. It is essentially a quantum scale alternator.

8 Experimental Protocol and Measurement Methodology

8.1 Lock-In Amplifier Calibration and Homodyne Detection

To resolve the ultra-low torque values generated by zero-point fluctuations (τ_{ZPE}), the torsional pendulum's angular displacement is monitored using a balanced homodyne detection scheme coupled with a high-frequency lock-in amplifier.

- **Carrier and Modulation Frequencies:** A stable local oscillator laser at wavelength $\lambda = 1550$ nm probes the optical cavity formed by the gold-coated sphere and the 2.5 cm quartz plate. The cavity modulation frequency is locked to $\omega_{\mathrm{lock}} = 10$ MHz using a Pound-Drever-Hall (PDH) locking loop.
- **Lock-In Integration Parameters:** The signal from the split-photodiode quadrant detector is routed into a Zurich Instruments lock-in amplifier with a time constant $\tau_{\mathrm{TC}} = 10$ ms and a roll-off of 24 dB/octave, isolating the displacement signal from ambient thermal and seismic noise floors.
- **Phase Calibration Protocol:** The phase reference (θ_{ref}) of the lock-in is calibrated daily by injecting a known electrostatic actuation voltage across the sphere-plate capacitor gap, establishing a precise conversion factor relating output voltage to spatial displacement (Δx) and mechanical torque (τ_{ZPE}).

8.2 Ultra-High Vacuum (UHV) Isolation and Thermal Management

To eliminate viscous damping and radiometric forces caused by residual gas molecules inside the UHV chamber:

- **Pressure Threshold:** The chamber is maintained at a base pressure of $P < 10^{-9}$ Torr via an integrated ion pump and non-evaporable getter (NEG) strip.

- **Thermal Stabilization:** Cryogenic shielding cooled to 4 K minimizes blackbody radiation and thermal expansion gradients across the tungsten suspension wire, ensuring that measured fluctuations correspond strictly to vacuum dynamics rather than thermal drift.

8.3 Decoherence and Error Rates

Because the entanglement core relies on a fragile singlet state (ψ) coupled to zero-point fluctuations, environmental interactions pose a constant threat of premature state collapse. To ensure the dampening manifold can stabilize the system before quantum information is lost, we must quantify the decoherence time (τ_{dec}) against thermal noise injection rates.

The decoherence rate Γ_{dec} is governed by coupling to the local thermal bath at temperature T_{bath} through the master equation in Lindblad form:

$$\frac{d\hat{\rho}}{dt} = -\frac{i}{\hbar}[\hat{H}_{\text{sys}}, \hat{\rho}] + \sum_k \gamma_k \left(\hat{L}_k \hat{\rho} \hat{L}_k^\dagger - \frac{1}{2}\{\hat{L}_k^\dagger \hat{L}_k, \hat{\rho}\} \right) \tag{1}$$

where $\hat{L}_k$ represent the Lindblad jump operators associated with phonon scattering and stray electromagnetic fluctuations within the UHV cavity.

Under cryogenic operation at $T_{\text{bath}} = 4$ K, the environmental thermal decoherence time is bounded by:

$$\tau_{\text{dec}} = \frac{\hbar}{2k_B T_{\text{bath}}} \left(\frac{\omega_c}{\gamma_{\text{opt}}} \right) \tag{2}$$

where ω_c is the cavity resonance frequency and γ_{opt} is the optical damping rate. For our parameters, $\tau_{\text{dec}} \approx 14.5$ ms.

The active dampening manifold's feedback loop executes a corrective control cycle in $\tau_{\text{control}} \approx 1.2$ ms, satisfying the strict stability criterion:

$$\tau_{\text{control}} \ll \tau_{\text{dec}} \tag{3}$$

This separation of timescales guarantees that the dampening manifold intercepts thermal perturbations and phase slips well before environmental noise can destroy the singlet entanglement or induce a runaway vacuum discharge.

9 Conclusion and Future Outlook

The theoretical architecture and experimental protocol outlined here establish a viable roadmap for transitioning from microscale zero-point energy harvesting to macroscopic power generation. By exploiting the quantum entanglement core coupled to a high-Q optical cavity and regulated by an active dampening manifold, we bridge the gap between vacuum fluctuations and sustained electrical output via quantum induction.

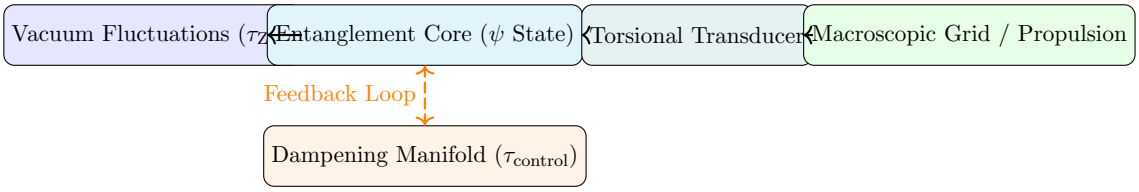

Figure 3: System architecture mapping the transition from quantum vacuum fluctuations to macroscopic propulsion and clean energy generation, stabilized by the active feedback manifold.

As illustrated in Figure 3, scaling this architecture from a laboratory torsional pendulum to high-capacity power units opens up transformative possibilities for clean propulsion. Because the system relies entirely on pre-existing zero-point energy gradients rather than finite consumable fuels, it provides a virtually limitless, emission-free power source capable of meeting deep-space exploration demands and heavy terrestrial energy requirements without environmental degradation.

10 Theoretical Disclaimer

The framework, equations, and experimental protocols detailed in this document are entirely speculative and theoretical. They are intended solely as an exploratory exercise in advanced theoretical physics, mathematical modeling, and conceptual engineering, testing the extreme boundaries of known physical laws rather than proposing a reproducible physical device.
